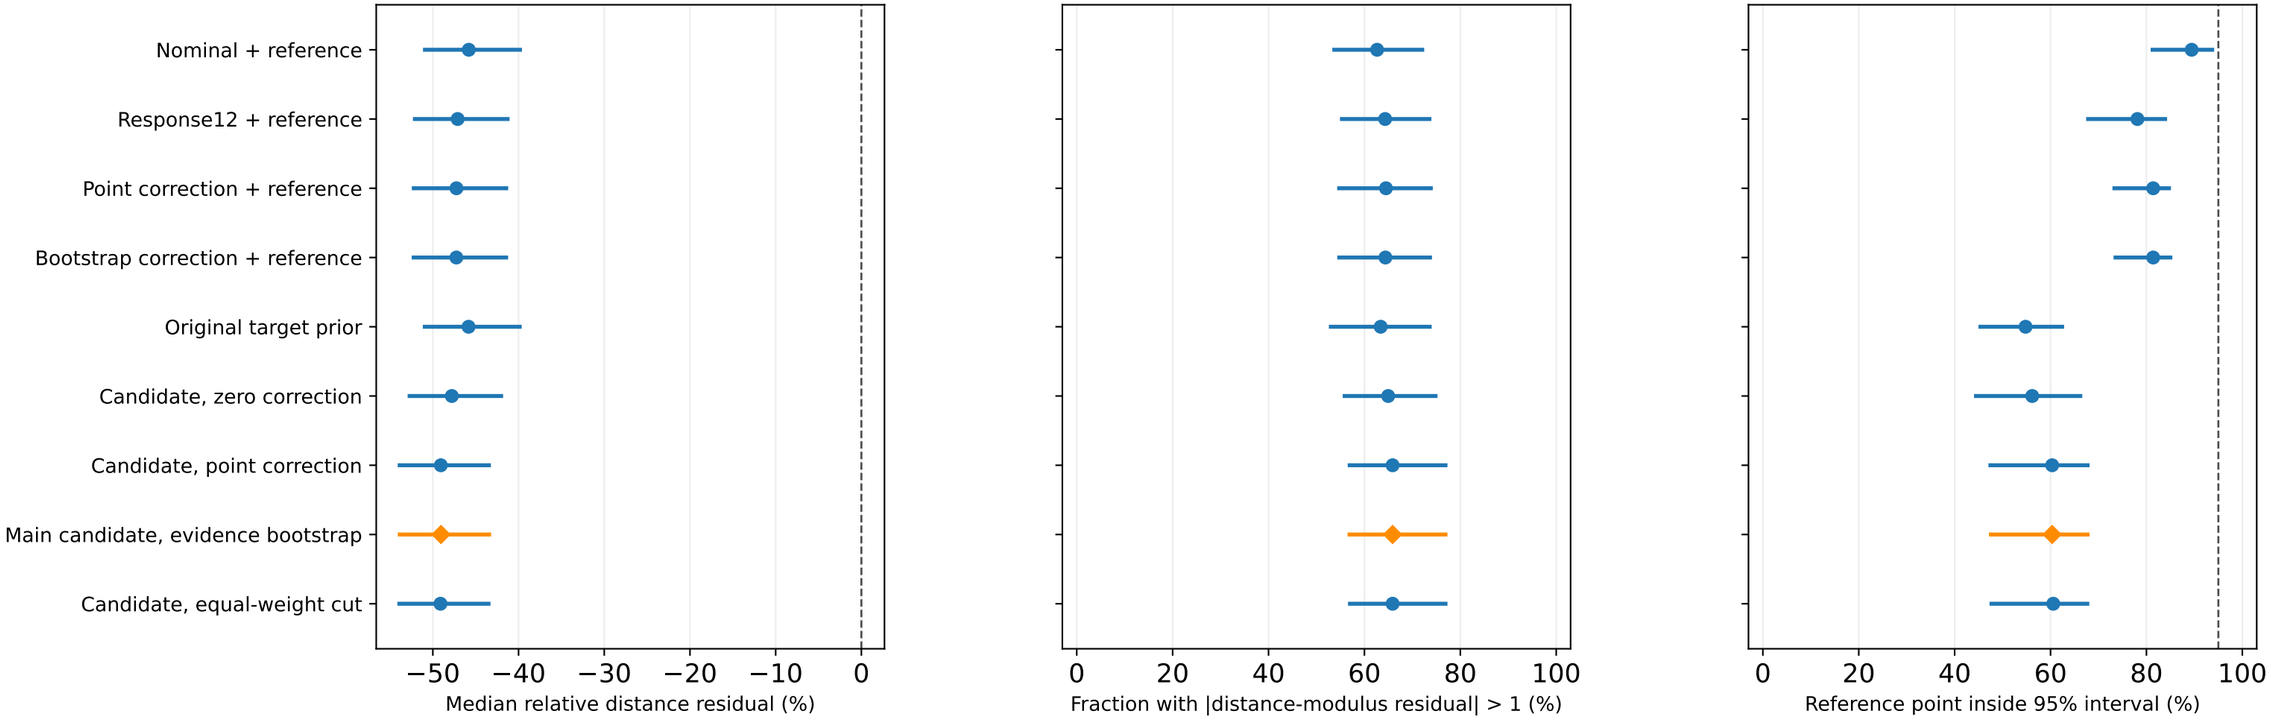
NGC 1261: one shared external distance scale

1732 frozen candidate-admission members | one HST kinematic scale | 4096 common reference-scale draws

Intervals reflect the shared reference-distance uncertainty, not 1732 independent distance measurements.

All objects and the main candidate evidence failure are retained. Orange: exact main candidate.



Reference-point agreement is not independently measured posterior coverage; the common-scale uncertainty is correlated across every member.

Shown: nominal method factor 1.00. Registered 0.97 / 1.03 sensitivities, all 3032 members and outside-domain objects remain in source tables.

This is validation of frozen photometric predictions. It does not refit a structure, resolve physical depth or establish fullcandidate contamination.
