Target evidence versus source-qualified transfer on seen development stars

Same frozen 256-star development design; each panel uses its qualified subset and original sampling weights.

Thin intervals resample whole sky cells. Higher scores are better; lower severe-error changes are better.

All matched response points and numerical failures are retained. These comparisons are diagnostics, not new independent validation.

Common teachers, overlapping references and the shared response family remain; target evidence gains do not imply calibrated real distances.
